

PROJECT HANDOVER

AI Sales Manager Agent

An autonomous agent that runs SynChem Global's outbound sales pipeline end to end: it assigns companies to salesmen weekly, chases meetings and outcomes, turns an approved deal into an invoice, and reports the whole thing live. Built standalone, structured to become an Odoo custom module later.

Where the project stands

AREA	STATUS	NOTE
Application	Complete	Full pipeline built and tested locally
Company data	Complete	4,962 companies imported and cleaned
Google Calendar	Complete	Working locally; needs two settings on the live site
Email	Complete	Branded HTML, sending; password needed on live site
Deployment	Partly done	Live and readable, but cannot save — database pending
Login / accounts	Not built	Deliberate — arrives with Odoo
Odoo module	Future phase	Schema already shaped for it

One thing blocks a usable live site. The deployed app can be opened and browsed, but every attempt to save fails, because Vercel's file system is read-only. A hosted database (Turso, free) must be connected before anyone can test properly. Roughly ten minutes of work — details on page 3.

What the system does

STEP	WHO	WHAT HAPPENS
1 Import	Manager	A CSV of companies is uploaded. A preview shows what will change before anything is saved; re-uploading updates rather than duplicates.
2 Assign	Agent	Every Monday at 09:00 each salesman is given their quota of companies, ranked and with a written reason for each pick.
3 Contact	Salesman	One tap opens WhatsApp with the message already written.
4 Meet	Salesman	A time agreed with the contact is recorded. Calendar invites go to the salesman, the contact and the manager; reminders fire 24 hours and 2 hours ahead.
5 Outcome	Salesman	Three questions: what happened, why, and was a sample requested.
6 Close	Agent	An approved deal raises an invoice and closes the company. A sample reduces stock. A follow-up date puts the company back on the list that day.
7 Review	Manager	A dashboard computed live from the data — never a static export.

PAGE TWO

What has been done

Everything below is built, working, and verified on a real run — not planned.

The data

SynChem's spreadsheet held 5,119 rows. It was profiled before any code was written, and several problems were found and handled:

- **4,962 companies** after merging **154 duplicates** that were listed twice under different spellings ("TECHNO FIRE (PVT.) LTD." and "Techno Fire"). Exact-name matching found none of these.
- The file is **Windows-1252, not UTF-8**. Read wrongly, "Nestlé" becomes "Nestl?". It is decoded correctly.
- **Only 89 companies have a usable email (1.8%)**, and twenty of those cells actually held phone numbers. This is why WhatsApp, not email, is the channel that reaches customers.
- **4,614 have a usable phone; 331 have neither** and can never be worked, so the agent skips them.
- 179 placeholder phones and a handful destroyed by Excel into scientific notation are flagged, not silently kept.
- "City" is a Lahore locality, not a city, and "Notes" hid the industry and contact name. Both were parsed into real fields.

Built and working

AREA	DETAIL
Weekly assignment	Ranked and explainable: follow-ups due first, then the salesman's own companies, then fresh leads in target industries with good contact data. Ranked on data quality alone the agent offered a chemicals salesman two banks, so an industry-fit term was added.
Meetings	Mostly in-person visits. The time is agreed with the contact, then recorded — by slot or by typing it. Clashes warn rather than block.
Calendars	Three layers: full Google Calendar sync per person, .ics invites by email, and a one-click "Add to Google Calendar" that needs no setup. Rescheduling moves the entry; cancelling removes it.
Reminders	Timed against each meeting, not a daily digest: about a day ahead to the salesman and the contact, then two hours ahead to the salesman. Never to the manager.
Outcomes & money	Approved raises an invoice; samples reduce stock through an append-only ledger. Nothing locks after entry — editing an outcome cancels rather than deletes an invoice, and never duplicates it.
Dashboard	Computed at request time from the operational tables. Charts use SynChem's own colours, validated so won and lost stay distinguishable to a colour-blind reader.
Safety	The company list is real. Messages to companies are blocked unless deliberately enabled, and a blocked message is permanent — adding credentials later cannot release a backlog of test messages.

How it was verified

- **21 automated safety checks** covering all four outbound modes, including that a retry cannot release held messages.
- The full pipeline run end to end: import, assign, book, approve, edit to rejected and back — one invoice throughout, stock counted once.
- Driven through the browser as both a salesman and a manager, on desktop and at phone width.
- Real emails delivered, all redirected to the test inbox. **No company was ever contacted.**

Deliverables: the application (50 source files, 4 commits), README.md for developers, TESTING.md for the team, and a shareable acceptance-test page for the project manager.

PAGE THREE

What remains

In the order it should be done.

Required before anyone can test the live site

#	TASK	WHY / HOW	TIME
1	Connect a hosted database	This is the blocker. Sign up free at turso.tech, create a database, and put its URL and token in the settings. Without it every save fails with a read-only error.	10 min
2	Add two passwords on Vercel	SMTP_PASS so email sends, and GOOGLE_CLIENT_SECRET so Calendar connects. They were left out deliberately — passwords should be entered by their owner.	5 min
3	Add the live redirect address to Google	In Google Cloud Console, add the live site's callback address to the OAuth client, or “Connect Google Calendar” will be refused on the live site.	2 min
4	Restore 15-minute reminders	Vercel's free plan runs scheduled jobs only once a day, and allows two. Reminders currently run daily, which is a real downgrade. A free external scheduler pointed at the reminder address restores the intended behaviour.	10 min

Known gaps — deliberate, not defects

GAP	POSITION
No login	You pick who you are from a menu. Anyone reaching the app can act as anyone, so it must not be shared publicly as it stands. Building it now would be discarded — Odoo brings its own accounts.
Placeholder products	Twenty invented chemical SKUs stand in until SynChem supplies the real catalogue. Replaceable from the Products page without code.
Team email addresses	Salesmen are set up on example addresses that will bounce. Real ones go in on the Team page.
WhatsApp not connected	Messages are composed and held, never delivered. Connecting a WhatsApp Business number would enable the channel that actually reaches these customers.
Industry labels	Some are wrong in SynChem's own file — Tariq Glass is filed under Cotton, along with 146 others. Faithfully preserved rather than guessed at; worth a pass on the source data.

The path to Odoo

The database tables were named after their Odoo counterparts from the first day, so the move is a mapping exercise rather than a redesign: company becomes res.partner, assignment becomes crm.lead, meetings become calendar.event, samples become stock.picking, invoices become account.move. Scheduling and messaging each sit behind a swappable interface for the same reason.

What carries over: the data, the business rules, and the domain design. What gets rewritten: the routes become Odoo controllers, the scheduler becomes ir.cron, and login becomes res.users. One honest caveat — Odoo generates its own tables from Python models, so the schema itself is a guide rather than something that transfers directly.

Recommended next step. Finish items 1 to 3 above, then hand the acceptance-test page to the project manager. That takes about twenty minutes and turns a demonstration into something the team can genuinely use.
